Review on Proniosomes

**Keywords:** Proniosomes, Surfactants, Formulation, characterization

**ABSTRACT**

The present article gives an elaborate study of proniosomes as a specialized drug delivery system. Proniosomes are thirst-preparation of water-soluble transporter particles that are covered with surfactant and can be slow out as desired and dry to form liposomal diffusion directly earlier use on brief worry in boiling aqueous media within minutes. Novel vesicular systems, such as proniosomes which is one of the advanced nanotechnologies which minimizes problems of vesicular systems such as aggregation, fusion, and leakage of drug and also minimizes additional transportation, distribution, storage, and dosing problem. Conventional vesicular systems such as niosomes and liposomes are faced in nature and stability related problems. The analysis object offers the vision about these methods lengthwise with a new vesicular method known as proniosomes. The concept proniosomes has demonstrated the potential in enhancing the oral bioavailability, targeting drugs to the specific site and also permeation of drugs across the stratum corneum. It prolongs the existence of the drug in systemic circulation and finally reduces the toxicity. The objective of this study is to introduce and develop proniosomes as a carrier system for various pharmaceutical applications.
INTRODUCTION

The development of novel drug delivery systems has received promising control of drug release in the body, which is either of temporal or spatial nature or both. The control drug action at a predetermined rate, or maintains a relatively constant, with minimization of undesirable side effects. It also localizes drug action by the spatial placement of control release systems adjacent to, or in the diseased tissue or organ; or target drug action by using carriers to deliver the drug to particular target cell type\(^1\). Several novel drug delivery systems are now available for various routes of administration, to achieve controlled and targeted drug delivery. Incorporation of the drug in vesicular structures is one such system, which can be assumed to prolong the release of the drug in the systemic circulation, and reduce the toxicity. Several vesicular drug delivery systems such as liposomes\(^2\), niosomes\(^3\), transfersomes, and pro vesicular systems like proliposomes and proniosomes have been developed\(^4\). Niosomes are unilamellar or multilamellar vesicles that are made up of non-ionic surfactants and can entrap amphiphilic and hydrophobic solutes\(^5\). Niosomes have shown advantages as drug carriers, such as being a cheap and chemically stable alternative to liposomes, but they are associated with problems related to physical stability, such as fusion, aggregation, sedimentation, and leakage on storage\(^6\). Proniosomes are the advanced niosomal formulation containing carrier and surfactant these are hydrated before using in the preparation. The hydration results in the formation of aqueous noisome dispersion. Proniosomes decreases the aggregation, leaking and fusion problem associated with niosomal formulation\(^7\).

PRONIOSOMES

Non-ionic surfactant vesicles known as niosomes are microscopic lamellar structures formed on the admixture of a non-ionic surfactant, cholesterol and diacetyl phosphate with subsequent hydration in aqueous media. Proniosomes provide a versatile novel vesicular drug delivery concept with the potential for the delivery of drugs through the transdermal route. Because proniosomes form niosomes upon hydration with water from the skin under suitable conditions. Proniosomes minimizes problems of niosomes like aggregation, fusion and leaking, and transportation, storage, dosing problems. The transdermal therapeutic system provides a considerable advantage over the non-invasive parenteral route for drug therapy, it avoids first-pass gut and hepatic metabolism decreases side effects. Provesicular systems had attracted researchers as an alternate strategy for the transdermal delivery of drugs because of
the non-toxicity and penetration effect of lecithin/surfactants. Provesicular systems have been exploited in oral drug delivery in the form of tablets, beads or capsules and have shown improved dissolution and absorption characteristics.

**ADVANTAGES OF PRO-NIOSOMES**

The advantages of pro-niosomes are as follows:

1. Proniosomes avoids the problems of physical stability such as fusion, aggregation, sedimentation, and leakage on storage.
2. Avoiding the problem of chemical stability like hydrolysis of encapsulated drugs which limits the shelf life of the dispersion.
3. Ease of storage and handling.
4. No difficulty in sterilization, transportation, distribution, storage uniformity of dose, and scale-up.
5. Drug delivery improves bioavailability and minimum side effects.
6. It shows controlled targeted and sustained release of drugs due to depot formation.
7. It can entrap both hydrophilic and hydrophobic drugs.
8. It is biodegradable, biocompatible, and non-immunogenic to the body.
9. The shape, size, composition, and fluidity of niosomes drug can be controlled when required.

**COMPONENTS OF PRONIOSOMES**

The essential components for the delivery system are as follows:

1 **Surfactants:**

Surfactants are the surface-active agent usually organic compounds that are having both hydrophobic and hydrophilic groups in nature. Therefore, surfactants contain both a water insoluble (hydrophobic) and a water soluble (hydrophilic) component. They can act as
wetting agents, emulsifiers, solubilizers and permeability enhancers\textsuperscript{12}. The most common non-ionic amphiphiles used for vesicle formation are as follows (Table)\textsuperscript{13}.

### 2 Carrier material:

The carrier when used in the proniosomes preparation. It permits the flexibility of the preparation in the ratio of surfactant and other components that incorporated. In addition to this, it increases the surface area and hence efficient loading. The carriers should be safe and non-toxic, free flowing, poor solubility in the loaded mixture solution and good water solubility for ease of hydration\textsuperscript{14–15}. Commonly used carriers are listed below Table.

### 3 Membrane stabilizer

Cholesterol and lecithin are mainly used as membrane preservatives. Steroids are important components of the cell membrane and their presence in membrane brings about significant changes in bilayer stability, fluidity, and permeability. Cholesterol is a naturally occurring steroid used as membrane additive. Cholesterol prevents aggregation of the formulation by repulsive steric or electrostatic effects. It leads to a transformation from the gel state to the
liquid phase in the vesicular systems. Phosphatidylcholine is a major component of lecithin. It has low solubility in water and can form liposomes, bilayer sheets or lamellar structures depending on hydration and temperature. Depending upon the source from which they are obtained they are as named as egg lecithin and soya lecithin. It acts as stabilizing as well as a penetration enhancer. It is found those vesicles composed of soya lecithin are larger than vesicles composed of egg lecithin probably due to the difference in the intrinsic composition\textsuperscript{16-17}.

4 Solvent and Aqueous phase

In the proniosomes formulation, alcohol is used because it has a great effect on vesicle size and drug penetration rate. Vesicles formed from different alcohols in that Ethanol have greater solubility in water hence leads to the formation of the highest size of vesicles instead of isopropanol which forms the smallest size of vesicle due to branched-chain present. Phosphate buffer pH 7.4, 0.1% glycerol, hot water is used as the aqueous phase in the preparation of proniosomes\textsuperscript{17}.

ACTION OF PRO-NIOSOME

Proniosome is a middle state of niosome formation as shown in Figure 1. The conversion of proniosome formulation into niosomes can be achieved by two-ways\textsuperscript{18-19}.

1. Hydration by the skin: The hydration is achieved by the skin itself, i.e., the water in the skin is used to hydrate the proniosome formulation and conversion to niosomes.

2. Hydration by solvents: Aqueous systems, i.e., purified water, saline solution, and buffers are used to convert proniosomes into niosomes with or without agitation and sonication\textsuperscript{20-21}.

![Figure No. 1: Action of niosome from proniosome](image-url)
FORMATION OF NIOSOMES FROM PRONIOSOMES

The niosomes can be prepared from the pro-niosomes by adding different types of the aqueous phase with the drug to the proniosomes with brief agitation, and the formation of niosome from the proniosome.

\[ T > T_m \]

Where, \( T \) = Temperature,

\( T_m \) = Mean phase transition temperature.

The formulation of niosomes from maltodextrin based proniosomes. This provides a rapid reconstitution of niosomes with the minimal residual carrier. In that slurry of maltodextrin, the surfactant was dried to form a free-flowing powder, which could be rehydrated by adding warm water\(^{22-25}\).

STRUCTURE OF PRONIOSOMES

Proniosomes are microscopic lamellar structures. These are a combination of non-ionic surfactant and cholesterol along with hydration by in aqueous media. The surfactant molecule directs themselves such that the hydrophilic ends of the non-ionic surfactant orient outward, while the hydrophobic ends are in the opposite direction to form the bilayer. Both the liposomes and proniosomes are made from the bilayer, but the liposome's bilayer is made up of phospholipids whereas the proniosomes bilayer is made up of non-ionic surface-active agents. The formation of unilamellar or multilamellar proniosome also depends on the method of preparation\(^{26}\).

The pro-niosome is made up of a surfactant bilayer with its hydrophilic ends exposed on the outside and inside of the vesicles while the hydrophobic chains (both) face each other within the bilayer. Hence the proniosomes can hold both hydrophilic as well as hydrophobic drugs. Hydrophilic drugs hold within the space enclosed in the vesicle and the hydrophobic drugs are embedded within the bilayer\(^{27}\).

Proniosomal gel is present in transparent, translucent or semisolid gel structure. The formed proniosomes are a mixture of phases of liquid crystal such as lamellar, hexagonal, and cubic because of limited solvent presence. Here, the lamellar phase showed sheets of surfactant
arranged in a bilayer, hexagonal phase which showed the cylindrical compact structure arranged in a hexagonal fashion whereas cubic phase consists of curved continuous lipid bilayer extending to three dimensions.

METHOD OF PREPARATION

Proniosome preparation mainly comprised of non-ionic surfactants, coating carriers, and membrane stabilizers. The formulation may be prepared by the following methods.

1 Slurry method

Proniosomes can be prepared by the addition of carrier and the entire surfactant solvent in a round-bottomed flask which is attached to the rotary flash evaporator and then a vacuum is applied to form a dry and free-flowing powder. Finally, the obtained formulation should be stored in a tightly closed container. The time required for proniosome production is not dependent on the ratio of the surfactant solution and appears to be stable. The advantage of this method is a uniform coating on the carrier and protects the active ingredients, surfactants from hydrolysis.

2 Slow spray coating method

The Preparation of proniosomes by slow spray coating method involves the spraying of surfactant in an organic solvent onto the carrier and then evaporating the solvent. This process is necessary to repeat until the desired surfactant loading has been achieved, due to the carrier is soluble in the organic solvent. The coating of surfactant on the carrier is very thin and hydration of this coating allows carrier dissolves. The obtained niosomes have uniform size distribution similar to those prepared by other conventional methods. The major advantage of this method is to provide a formulation of hydrophobic drugs in a lipid suspension with or without a problem. It is also found to interfere with the encapsulation of certain drugs.

3 Co-acervation phase separation method

It is extensively used for the formulation of proniosomal gel. In this method, cholesterol, surfactant, and drug are dissolved in a suitable solvent in a wide-mouthed glass vial. After Mixing the glass vial is covered with a lid to prevent the loss of solvent because the solvent is heating in a water bath. This process is repeated until the surfactants are dissolved.
completely. Then, add a little amount of aqueous phase to get gel formation and not the dispersion, for example, diluted glycerol solution, and phosphate buffer. The above solution on the water bath is warmed until a clear solution is obtained, then which on cooling it converts into a Proniosomal gel as shown in Figure 2. The obtained gel is stored in the same glass tube in a dark place for characterization. After hydration of proniosomes gets converted into uniformly-sized niosomes\textsuperscript{36-37}.

CONCLUSION

Proniosomes contain both nonionic surfactant and phospholipids, both can act as penetration enhancers and useful in increasing permeation of many drugs. These carrier systems have more scope in the future, particularly within the area of transdermal drug delivery. The provesicular systems have been gaining a lot of interest from various researchers and scholars, because of their advantages of prolonged and sustained release action, versatility and stability as a drug carrier. But future experiments should explore the quality and suitability of proniosomes with more drugs designed and improves effectiveness for intended therapy. So, that proniosomes are described as promising drug carriers and promising drug delivery modules.
